Abstract

The electrochemical method is efficient, cost effective, and environmentally friendly process. Copper nanopowder has been known, as a nontoxic, inexpensive, highly conductive, excellent microbial agent, catalytic, and sensors applicable. Copper nanopowder was prepared by an electrochemical method under various conditions. The effect of type and concentration of electrolyte solution, and the sample treated with thiourea and ascorbic acid on the size and purity of copper nanopowder was investigated. Two different salts copper: sulfate and nitrate aqueous solutions ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$), $\text{Cu}(\text{NO}_3)_2 \cdot 5\text{H}_2\text{O}$ were used to produce copper nanopowder. The synthesized copper nanopowder was identified using X-ray diffraction (XRD), the scanning electron microscope (SEM), and Energy Dispersive Spectrum (EDS). The results of XRD patterns revealed a high degree of crystallinity, monophasic nature, and pure copper powder with no impurities or oxides observed for both electrolyte solutions after treated with 2 percent of ascorbic acid. It was confirmed that particle size at room temperature was as small as 25nm when the copper nitrate is used as an electrolyte solution compared to copper sulfate (41nm).

1. Introduction

The synthesis of metal Nanopowders has being given considerable attention due to their unique physical and chemical properties. Nanoparticles possess a high surface-to-volume ratio owing to their small size. This feature has attracted many researchers to widely investigate nanomaterials and their applications. Metallic nanoparticles have been vastly used for numerous applications, such as catalysis, solar energy, optical, magnetic, thermal, biological sensors, synthesis of chemical composite, and medicine [1-3].

Several methods have been utilized to prepare the metallic Nanopowder, such as chemical, physical, and biological reduction methods. Each one of these synthesis methods has advantages and disadvantages in producing metallic nanopowder. The chosen synthesis method needs to consider numerous agents, some of them related to shape, size of the nanoparticles, and other concerns to cost, level of production, and hazard. Electrochemical deposition technique is among the most important appropriate, simple, fast, high throughput, and economical methods which are used for a diversity of materials including copper nanopowder[4, 5].

This method is relatively clean, non-toxic, environmentally friendly, and it can be done under room temperature using copper salts as an electrolytic solution. The problem that still occurs in synthesis with electrochemistry is

the existence of ionic interactions and nonuniform splits for the grains particle size. Many parameters have an effect on the morphology of copper nanopowder, such as overvoltage, level of released hydrogen, current density, concentration of copper ion, pH, temperature, distance and materials of electrodes, etc. [4].

Copper nanopowder has excellent electrical and thermal properties make it an important in many industrial applications such as photochemical catalysis, biosensing, gas sensor, electrochemical sensing and solar/photovoltaic energy conversion, lubrications, nanofluids, conductive films, conductive ink, & conductive paste for printed electronics, and antimicrobial agents. Copper nanopowder showed antifungals and insecticidal activity against the pests of crop plants. It can be used as fertilizers, herbicides, and pesticides[6]. The copper nanoparticles are preferred in many applications compare with other metallic nanopowder such as gold and silver nanopowder owing to the cost effective and the physical and chemical stability [7-10].

In this work, we try to overcome the electrochemical method problems to produce homogenous pure copper nanopowder. The effect of type and concentrations of electrolyte solutions, current density, the addition of thiourea and ascorbic acid, on the size and purity of copper nanopowder was studied. Two different types of copper salts ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$), $\text{Cu}(\text{NO}_3)_2 \cdot 5\text{H}_2\text{O}$ were used to produce copper nanopowder. X-ray diffraction (XRD), scanning electron microscope (SEM), and Energy Dispersive Spectrum (EDS) were used to investigate the powder purity, shape, and particle size of synthesized copper nanopowder.

2. Materials and Methods

Two rods of 99.99% copper were used as the cathode and the anode. ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$) $\geq 98\%$, ($\text{Cu}(\text{NO}_3)_2 \cdot 5\text{H}_2\text{O}$) $\geq 98\%$, ascorbic acid, acetone, thiourea 99%, ethanol was purchased from Sigma-Aldrich. H_2SO_4 was purchased from Merck.

2.1 Synthesis of Copper Nanopowder

2.1.1 The Electrochemical Cell

Two cylindrical shape, with a length of 15 cm and a diameter of 2 mm of high purity copper (999.99%) were used as the two electrodes in the cathodic electrochemical cell. The electrodes were washed with deionized water (DI) and polished with very fine sand paper (220 grit). Afterward, they were washed with DI water. After drying in ambient temperature, the wires promptly immersed in ten percent of H_2SO_4 bath for five minutes, then placed in the ultrasonic bath for five minutes to remove the surface oxide layer. The electrodes were washed out again with DI water and then placed into the electrolyte solution. Electrolysis was carried out at a temperature of 27.0 ± 0.5 °C in an open cell of cylindrical shape. The rode of copper electrodes was positioned at a distance of about 2 cm from each other as shown in Figure (1) [1, 7].

2.1.2 Electrolyte Solutions and Additives

Two types of Electrolyte solutions were prepared using salts copper: sulfate ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$) and nitrate, $\text{Cu}(\text{NO}_3)_2 \cdot 5\text{H}_2\text{O}$. Three concentrations of each salt were used (0.1M, 0.5M and 1M). Two types of antioxidants were added separately to the electrolyte solution in various concentrations, 0.02% thiourea and 2% Ascorbic acid. The synthesized nanopowder was collected from all experimental conditions for characterization.

Current densities of 0.8, 1.5, 2 A/cm^2 were used. The current was Reversed every two minutes. The precipitated copper nanopowder is deposited as a superfine coat powder on the surface of the cathode electrode. Each test was run for five hours. The precipitated copper nanopowder was separated from the electrolyte solution as shown in Figure (2) by centrifugation for 3 minutes at 13000 rpm, then washed with DI water for three times. A small amount of acetone was added to the powder, and then the samples dried out in the air atmosphere.

2.2 Characterization

In order to identify and confirm the purity, the powder was characterized by the X-ray diffraction (XRD), with a $\text{Cu-K}\alpha$ radiation using an Angstrom Advanced XRD model ADX2700 diffractometer (USA) equipped with a graphite monochromator and operated at 40 kV accelerating voltage and 30 mA current. The test was performed using a stepscanning program with 0.05° per step and acquisition time of 5 seconds per step at 2-theta and a scanning range of $10\text{--}90^\circ$. The XRD data were analyzed using jade 6.5, which contains the information of the Committee for Powder Diffraction Standards (JCPDS). The surface morphological and purity characterization is done using scanning electron microscopy (SEM) type FEI INSPECT S50.

3. Results and Discussion

Electrochemical deposition is a trustworthy method for many reasons; it is simple, economic, highly productive, and eco-friendly. However, a variety of problems are associated with this method, such as producing undesirable ions, besides that there is an issue of producing samples with different shape and size. The power supply provides a constant current to one of the two electrodes pushing the positive ions to pass through the electrolyte solution to the second electrode. During this process, chemical changes will occur. The dissociation process of the electrolyte and dissociated ions could be shown at the electrodes. Three different current densities (0.8, 1.5, 2 A/cm²) were used. However, the rise of the current density led to an increase in the size of copper powder which reaches to micrometre in size (data are not shown here). The releasing process of copper nanoparticles from one electrode to the second could happen too. The copper nanoparticle was removed by reversing current flow for two minutes manually. The deposited copper nanoparticles were collected by centrifuging the sample at 13000 rpm for three minutes and washed several times with distilled water to remove the impurities. A small amount of acetone was added to prevent oxidation. The sample then dried out in the air atmosphere [5].

Figure (2). Synthesized Copper Nanopowder.

X-ray diffraction is a Powerful and rapid characterization technique used in solid-state materials. The pattern of diffraction provides information on the shape and size of the unit cell and the information of electron density inside the unit cell and peak positions, specifically where the atoms are located from peak intensities [11]. The

indexing procedure of powder diffraction pattern was achieved and Miller Indices (hkl) for all peaks were assigned. Jade 6.5 software was used to estimate the average particle size, which is calculated from Debye-Scherrer formula. X-Ray Diffraction was achieved to describe the effect of electrolyte solutions and their additives on particles crystallinity and the purity of copper nanopowder comparing with the standard ICDD card. Different concentrations of copper sulphate were used (0.1, 0.5 and 1M). The results of XRD show that the low concentration of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ leads to an increase in Cu nanopowder oxidation and almost the participated powder was copper oxide as shown in Figure (3). The 2θ of 29.381° , 36.26° , 42.139° , 52.295° , 61.221° , 69.357° , 73.417° , and 77.239° correspond to (110), (111), (200), (211), (220), (310), (311) and (222) crystal planes of Cu_2O . However, the nanopowder with 1M concentration is showing a mix of nanocopper and nanocopper oxide as exhibited in Figure (4), and the size of the crystals is 41 nm. The 2θ of 29.279° , 36.199° , 42.041° , 52.312° , 61.160° , 73.380° , and 77.219° correspond to (110), (111), (200), (211), (220), (311), and (222) crystal planes of Cu_2O and 43.119° , 50.398° , and 73.899° correspond to (111), (200), and (220) crystal planes of Cu, which confirm face centred cubic (FCC) crystal lattice of both.

Figure (3). XRD result of copper nanopowder of 0.5M $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ electrolyte solution .

Figure (4). Nanopowder of 1M $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ electrolyte solution.

The XRD patterns of nanopowder that was obtained from using 1M $\text{Cu}(\text{NO}_3)_2 \cdot 5\text{H}_2\text{O}$ as electrolyte solution is quite similar to that of 1M $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ as shown in Figure (5). The peaks at 2θ of 36.392° , 42.248° , 52.391° , 61.303° , 73.494° , and 77.265° correspond to (110), (111), (200), (211), (220), (311), and (222) crystal planes of

Cu₂O and the peaks at 2θ of 43.257, 50.433, and 74.090° correspond to (111), (200), and (220) crystal planes of Cu. The value of the average crystallite size was 25 nm.

Figure (5). Copper nanopowder of 1M Cu(NO₃)₂ 5H₂O electrolyte solution.

Two types of antioxidants thiourea and ascorbic acid were added to the electrolyte solutions to prevent the oxidation of copper nanopowder during the process of electrochemical analysis. The XRD patterns of nanopowder that obtained after adding 0.02 % of thiourea to the 1M Cu(NO₃)₂5H₂O electrolyte solution are shown in Figure (6). The peaks were at 2θ of 12.228, 16.104, 29.025, 35.899, 41.852, 42.702, 49.9, 51.865, 52.592, 53.012, 60.95, 66.901, 73.3, and 76.942°. However, the peaks at 2θ of 29.025, 53.012, 60.95, and 73.3° corresponding to (101), (200), (104), and (114), respectively, which indicating of Cu₂S and the results confirm the impurity of the sample. The 2θ peaks at 42.702, 49.9 and 73.3° demonstrate for a shift in 2θ angles of phases of copper and copper oxide nanopowder. It could be the mixed nanopowder of cover with Cu₂S and thiourea [12]. The calculated crystals' size is 16 nm. In spite of the small size that was gotten from this treatment. The impurity of the sample made it unsuitable process to produce copper nanopowder.

Figure (6). Copper nanopowder of 0.02 % thiourea with 1M CuSO₄·5H₂O electrolyte solution.

The nanopowder that obtained from electrolytic method using of two different electrolyte solutions was treated with 2% ascorbic acid as illustrated in Figure (7). The results of XRD show no peaks of impurities or reflections of 2θ angles. The peaks at 43.160, 50.295, and 73.952° are attributed to the (111), (200) and (220) planes. These peaks are characteristics of the face-centered cubic (FCC) structure of metallic copper and no diffractions of the crystallographic impurities are found. In fact, there are energetically distinct sites on each crystallographic facet, which is based on the density of an atom. The highest atom density facets for copper nanopowder are recognized to be highly reactive (111). For a phase center materials have a high intense peak at (111) reflection that (hkl) all odd or all even. Peaks of diffraction correspond well with ICDD cards No. 99-0034 are observed [5].

Figure (7). Copper nanopowder of 1M Cu (NO₃)₂·5H₂O electrolyte solution after treated with 2% ascorbic acid.

The results of SEM for synthesized copper nanopowder which is characterized morphologically and nano-structurally are shown in Figure (8). SEM image indicates the dot shaped and highly crystalline copper nanopowder and the appearance of individual particles is spherical in shape. The size of the Cu nanopowder was measured by image J software which was approximately 18 nm. However, in lower resolution, we can notice

some large particles, which could be accumulated from forming Van Der Waals clusters of smaller particles [5].

Figure (8). SEM micrographic image of synthesized copper nanopowder.

The sample was determined by Energy Dispersive Spectrum (EDS) measurement. The EDS indicates that the major chemical element of synthesized copper nanopowder is copper with a small amount of C and O. No impurity elements were detected as illustrated in Figure (9).

Figure (9). EDS Spectrum of copper nanopowder.

4. Conclusions

Electrochemical method is considered as an efficient, cost effective, and environmentally friendly process. The method of synthesizing has a noticeable effect on the particle structure characteristics such as size and morphology. It can conclude the shape and size of copper and purity of the nanopowder are affected by the concentration of electrolyte solution, current density, and the addition or treatment of the produced powder. The nanopowders were synthesized using two different salts (copper:sulfate and nitrate aqueous solutions). The synthesized nanopowder was a mixed of nanocopper and nanocopper oxide with particles size of 41 and 25 nm, respectively. The nanopowder that treated with 2% ascorbic acid was high purity spherical shape with a size of around 18 nm.
