Temperature dependence of Ion Association of Tetra Aqua (1, 10 – phenathroline) Nickel (II) Chloride in Ethanol –Water mixture

Y.O.Hamed – Allaf

Chemistry Department, College of Science, Mosul University, Mosul, Iraq

Abstract

The ion association constant (K_A) of [Ni(1,10 phenathroline)(H₂O)₄] Cl₂, has been determined by conductivity measurements at 278.15-318.15 K. it is found that the order of magnitude of K_A at any temperature at different percentage of ethanol – water mixture decrease with decreasing ethanol percentage and increasing the temperature. The enthalpy, gibs free energy and entropy increase with increasing ethanol percentage and temperature, this can be attributed to the decrease in the fraction of the contact ion pairs formed by the hydrogen bonding between the polar hydrogen of the complex and solvent atoms. The data were analyzed using Lee – Wheaton equation to calculate: (Λ_0 , K_A & R) equivalent conductance Λ_0 , association constant K_A and the main distance between ion in solution R. Walden product ($\Lambda_0 \eta_0$) have also been calculated for each solvent composition, a relationship was found to exist between the ($\Lambda_0 \eta_0$) and 1/D of the medium which indicate the tendency of the association of ions.

Key word: Conductivity, Lee-Wheaton equation, thermodynamics, Walden product.

Introduction

The analytical application of complexes of Mn,Ni,Co. ions with 1,10 phenathroline as a ligand which have very wide application in industry and have a biological effects screened against a number of fungi and bacteria to asses their growth inhibiting potential were studied by Lee-Wheaton equation to investigate their behaviour of interaction by conductivity⁽¹⁾.

The possible importance of such properties as solubility partition coefficient, surface activity, degree of dissociation , inter atomic distance between functional group , hydrogen bonding , chelation and the spatial configuration of the molecules are worthy of consideration $^{(2)}$

Conductivity measurements over awide temperature range for electrolytesolution can provide detailed information concerning ion - ion and ion -solvent interaction especially from the thermodynamic view point ⁽³⁾.

Molar conductivities of NaBr electrolyte in 2-butanol + water mixtures were measured in the temperature range from 5°C to 45 °C at 10 °C intervals⁽⁵⁾, also molar conductivity of HBr in 2-propanol + water mixtures was determined at five temperatures in the region from 288.15 to 308.15 K .Data were processed by the Lee-Wheaton conductivity equation with parameter R and the following quantities were obtained: Limiting molar conductivity (Λ_o), association constant (K_A) and thermodynamic quantities for the ion association reaction ⁽⁵⁾.

From a conductometric study at temperatures between 278.15 and 318.15 K of $[Ni(phen)(H_2O)_4]Cl_2$, it is clear that the ion association constant (K_A) is smaller at 45 °C and increase with decreasing temperature . in the order $K_A > K_A > K_A > K_A > K_A > K_A 5$ °C 15 °C 25 °C 35 °C 45 °C The remarkable increase in the K_A values with decreasing temperature as well as the relatively small entropy and enthalpy changes were ascribed to the specific short –range interaction, such as hydrogen bonding between the amine hydrogen atoms of the complex and the oxygen atoms of anions in the contact

ion pairs. To confirm the validity of the above interpretation and to investigation the dependence of the ion – association behavior on the properties of the complex ions, the association of tetra-aquo (1,10 phenathroline) Nickel (II) chloride in ethanol –water mixture were studied by measuring the conductivities at different percentages and temperatures to know detailed information concerning their thermodynamics and may be used for the understanding of the electrochemical reaction mechanism.

Experimental

Preparation of complex:

In order to prepare the desired complex ⁽⁶⁾, a mixture of 2 mM of 1,10 phenathroline in 10 cm³ of ethanol and 2 mM of NiCl₂.6H₂O in 30 cm³ of deionized water was refluxed for about 45 min on a water bath. On cooling and adding excess of absolute ethanol the complex was precipitated, filtered then washed with ice cold 50% ethanol and then recrystalized by slow cooling to 0 °C followed by addition of excess absolute ethanol . the product was dried under vacuum over anhydrous calcium chloride .Ethanolwas purified and dried by the method described by Perrin⁽⁷⁾ and the procedure repeated twice to ensure that all water was removed. Magnetic electronic spectral, (UV), infrared measurements used for analysis of the complex and also gas chromatography was used to determine the water content and other organic impurities of the purified ethanol as a solvent. Conductivity measurements were made using a (WTW) conductivity meter (Model LBR) with frequency range of 50 Hz -30 KHz and sensitivity between 10^{-1} and 10^{-9} S.

Purification of solvents:

For conductivity measurement in any solvent a especial design is required to ensure complete isolation of the system from outside atmosphere and to maintain the isolation during the addition of solute . Nitrogen gas was passed through lime water, sulphuric acid calcium chloride before interning the cell . The temperature of the cell and its contents was kept constant at certain

temperature $(\pm~0.1~^{o}C)$ using water circulating ultra thermostat type VHS ~B radiometer . Purified nitrogen was passed through a known volume of solvent until the conductance of the solvent was constant , addition of solute were then made .

Tools and method:

The design of the conductance cell and the nitrogen line was the same as that previously used by Wheaton ⁽⁸⁾. The cell constant for the conductivity cell was measured using the methods of Jones and Bradshow⁽⁹⁾. 0.01 M KCl solution was prepared from KCl (BDH reagent) recrystallized three times from conductivity water and then dried at 760 Torr and 500 °C for10 hr.The cell constant was checked regularly and found to be 0.0554 cm⁻¹.

A general method has been used for measuring the conductance of electrolytes . The conductivity cell was washed first with conductivity water and then with methanol then dried, weight empty and kept at constant temperature, Purified nitrogen gas was passed for 10-15 min until the conductance of the solvent was constant, whereupon the cell plus the contents were weighed . A certain amount of solution was injected in to the conductivity cell from a plastic syringe (which was weighed before and after each addition), then nitrogen gas was passed . Small increment of known amount of the complex solution were then added (generally 10 additions) and the conductivity of the solution was measured after each addition . After all additions have been made, the cell was reweighed to find the weight change over the whole run.

It was found that the maximum weight loss in a single run was not more than 0.02 % .

Results and discussion

The electrical conductivity of the desired complex have been studied in ethanol- water mixture at different temperatures to investigate the dependence of the ion association behavior on the properties of the complex ion . The data were treated using LW method in which a wide temperature range for electrolyte solution can provide detailed information concerning ion – ion and ion – solvent interaction especially from thermodynamic point of view⁽¹⁰⁾.

For an unsymmetrical electrolyte MX_2 ionizing to M^{+2} and X^{-} the possible association equilibria are :

$$M^{+2} + X^{-1} \xrightarrow{K_A^{(1)}} MX^+$$

 $M^+ + X^{-1} \xrightarrow{K_A^{(2)}} MX_2$

Thus three ionic species are present in the solution which are $M^{\pm 2,}\ MX^{\pm}$ and X^{\pm} . All such solutions are in effect " mixed electrolyte " solution since the ion pair MX^{\pm} is a conducting species .

$$\Lambda_{\text{equiv.}} = \sum_{i=1}^{S} Z_{i}^{\dagger} m_{i}^{\dagger} \lambda_{i} C^{\dagger}$$
This equation is derived as follows
$$\lambda_{i} = f(\lambda^{\circ}_{i}, \varepsilon K, R)$$

$$\sigma_{i} = i \lambda_{i} / 1000 = Z_{i} m_{i} \lambda_{i} / 1000$$
and
$$\sigma_{\text{solu.}} = \sum_{i=1}^{S} C_{i}$$
or 1000 $\sigma_{\text{osolu.}} = \sum_{i=1}^{S} C_{i} \lambda_{i}$
and
$$\Lambda_{\text{solu.}} = \sum_{i=1}^{S} Z_{i} | m_{i} \lambda_{i} | / \Sigma C_{i}$$

where (s) is the number of ionic species , σ is specific conductance, C stoichiometric equivalent concentration , λ_i , m_i , C_i and Z_i are the equivalent conductance , molar free ion concentration , equivalent concentration and charge of the ith species respectively . thus for 2:1 associated salts :

 $\Lambda_{MX}^{+2} = f(\lambda_{M}^{o})^{+2}, \lambda_{MX}^{o}, \lambda_{X}^{o}, K_{A}^{(1)}, K_{A}^{(2)}, R^{(2)}$

Where R is the average center to center distance for the ion pairs , A multi – parameter " Least square " curve - fitting procedure is used to give the lowest value of curve fitting parameter σ (A) between the experimental and calculated points . An iterative numerical method which was found to be very successful has been used to find the minimum $\sigma \Lambda^{(8)}$

$$\sigma \Lambda = \left[\sum_{n=1}^{N_p} (\Lambda_{\text{Calc.}} - \Lambda_{\text{exper.}})^2 / N_p\right]^{1/2}$$

A program (RM₁) is used to analysis the concentration conductivity measurements in which the input data are (T, D, η) where T is the temperature in Kelvin , D and η are the dielectric constant and viscosity (poise) of the solvent at that temperature ⁽¹⁰⁾.

Tables (1-5) show the conductivity - concentration data for the studied complex in different percentage at different temperatures . The plots of $\Lambda_{equiv.}$ Against the square root of the molar concentration (C $^{1/2}$) are shown in figures (1 A-B) as an example . From tables and figure. It can be seen generally that the equivalent conductivity increase with increasing the temperature and increasing the percentage of water because of increase except for 80% EtOH were the equivalent conductivity decrease because of formation of ionsolvent bonds between the complex ion and ethanol from one side and between the complex ion water from the other side (hydrogen bonding) , the electrostatic power of attraction between two ions F (r) is equal to $e^2 Z$

 $^{+}Z^{-}/$ Dr², where Z $^{+}Z^{-}$ are the charges of the ions apart from each other in a distance equal to (r), e : equal to 1.206 x 10⁻¹⁸ coulomb, D is the dielectric constant of the solvent where the value of F(r) is the smallest if D is large ⁽¹¹⁾.

The ionic atmosphere has another effect on the motion of the ions since moving ion experience a viscous drag, when the ionic atmosphere is present this drag is enhanced because the ionic atmosphere moves in an apposite direction to the central ion, The enhanced viscous drag, which is called theelectrophoretic effect reduces the mobilities of the ions and hence also reduces their conductivities which leads to decreasing equivalent conductance ⁽¹²⁾.

Fig (1): The plot of equivalent conductivity against the square root of molar concentration for [Ni (1,10 – phenathroline)(H₂O)₄]Cl₂ ethanol ethanol water mixture at 298.15 K

Fig (2): The plot of equivalent conductivity against the square root of molar concentration for [Ni (1,10 – phenathroline)(H₂O)₄]Cl₂ in ethanol ethanol water mixture at 318.15 K

Table (6) show the analysis of data by using Lee-Wheaton equation for unsymmetrical electrolyte which indicates that he values of K_A decrease with increasing temperature . This may be attributed to the short range interaction and the hydrogen bonding formed at low temperature . The results of the distances parameter R show that the complex electrolytes form solvent separated generally (49-53.3) which means that the cation is separated by a large numbers of solvent molecules from the anion .

The value of λ_M +2 (the ionic equivalent conductance) increase as water percentage increase and increasing temperature, this also because of broking the hydrogen bond as temperature increase and of increasing dielectric constant of the mixed solvent. And finally the value of λ_{MX} +1 is very small since it is a large ion and convert easily to the product MX₂.

The small values of σ (Λ) give an indication of the good best fit values of less than (0.1).

Table (6): The result of analysis of $[Ni(phen)(H_2O)_4]$ Cl_2 at different percentages and temperatures .

The plot of ln K_A against (1/T) (Arrhenius equation) (ln $K_A{=}$ - $\Delta H^o{\!/}$ RT+C)is shown in figure (3) for the complex

in different percentage of ethanol – water mixture which are linear .

Fig (3) :The plot of Ln K_A against (1/T) for [Ni(phen)(H₂O)₄]Cl₂ in ethanol water mixture at different temperatures.

Thermodynamic parameters ΔH^o , ΔG^o , ΔS^o , are determined from the following :

 ΔG° and ΔH° are determined from values of $K_A(\Delta G^{\circ}=-RT\ Ln\ K_A)$ and temperature, ΔS° is calculated from these two parameters ($\Delta G^{\circ}=\ \Delta H^{\circ}-T\ \Delta S^{\circ}$)Which are given in table (7). It is well known that addition of an electrolyte to a solvent causes some structure change due to the rupture of the bonds between the solvent molecules from one side and to the interaction of ions with each other and with the solvent molecules from the other side $^{(12)}$. The negative entropy provides a good indication of ionic association which has an ordering effect on the solution . The solvation effect i.e. interaction of the ions with the solvent molecules may exert on the solution structure in

the same manner leading relatively to a decrease in the entropy as temperature increase and decrease with increasing water percentage ⁽¹³⁾.

The enthalpy of activation according to the activated complex theory $^{(14)}$ is a result of the energies being expended for the destruction of the solvent-solvent bonds and the formation of solvent – ion bonds . As can be noticed from Table (7) , ΔH^o increase with increasing water percentage until %60 and then decrease as water percentage increase due to the broken of ion – ion bond in solution because of increasing the dielectric constant of the solvent $^{(15)}$. Finally , the values of ΔG^o are negative according to the relation (ΔG^o =-RT Ln K_A)which indicate the reaction is spontaneous .

Table (7): $-\Delta G^{\circ}$ KJmole⁻¹ of ion association in ethanol – wate mixture at different temperatures.

Fig (4) Temperature dependence of ΔG of [Ni(phen)(H₂O)₄] Cl₂in ethanol-water mixture at different temperatures.

Fig (5): Variation of Walden product with the reciprocal of electric constant of [Ni(phen)(H₂O)₄]Cl₂ in ethanol water mixture at 298.15 K

Fig (4) show that the values of $-\Delta G$ for the complex gradually decrease with increasing temperature .This is attributed to the fact that the contribution of directional interactions around the nitrogen to ion association is Larger. The directional interactions of [Ni(phen) (H₂O)₄] with Cl⁻ are more distributed by its rotational motion strengthened with increasing temperature ⁽¹⁶⁾. The variation of Walden product ($\Lambda_o \eta_o$) would be constant only if the effective radius of the ion remains the same in

the different media . since most ions are solvated in solution to different extent , the dimensions of the moving unit will undoubtedly vary to

some extent and exact constancy of the conductance viscosity product is not to be expected. This is the case in the behavior of the present system as indicate in fig.(4) where the cations are expected to suffer various degree of solvation with increasing amount of ethanol in ethanol – water mixtures $^{(17)}$.

تأثير درجة الحرارة على ثابت التجمع الايوني للمعقد Cl₂[Ni(phen)₂(H₂O)₄]Cl₂ تأثير درجة الحرارة في مذيب الايثانول والماء بنسب مختلفة

ياسر عمر حميد العلاف

قسم الكيمياء ، كلية العلوم ، جامعة الموصل، الموصل ، جمهورية العراق

الملخص

تم قياس ثابت التجمع الايوني للمعقد $Cl_2(H_2O)_4$ Cl_2 في مدى لدرجات لحرارة (K) (K) 318.5-318.15 بواسطة تقنية التوصيليية وبتطبيق معادلة لي – ويتون لتحديد قيمة ثابت التجمع الايوني (K_A) في كل درجة حرارة ولكل نسبة من مذيب الايثانول والماء ووجد بان قيمة (K_A) نقل كلما قلت نسبة الايثانول وزادت درجة الحرارة ووجد كذلك بان قيمة حرارة التفاعل (ΔH) والطاقة الحرة (ΔG) والعشوائية (ΔS) تزداد بزيادة نسبة الايثانول ودرجة الحرارة ويعود السبب في ذلك الى قلم الناتج الجزيئي لتداخل الايونات المتكون نتيجة الاصرة الحرة (ΔG) والعشوائية (ΔG) تزداد بزيادة نسبة الايثانول ودرجة الحرارة ويعود السبب في ذلك الى قلة الناتج الجزيئي لتداخل الايونات المتكون نتيجة الاصرة الهيدروجينية بين المعقد وجزئية المذيب وحسبت كذلك الدوال الحرارة ويعود السبب في ذلك الى قلة الناتج الجزيئي لتداخل الايونات المتكون نتيجة الاصرة الهيدروجينية بين المعقد وجزئية المذيب وحسبت كذلك الدوال التوان ويعود السبب في ذلك الى قلة الناتج الجزيئي لتداخل الايونات المتكون نتيجة الاصرة الهيدروجينية بين المعقد وجزئية المذيب وحسبت كذلك الدوال الترازة ويعود السبب في ذلك الى قلم الناتج الجزيئي لتداخل الايونات المتكون نتيجة الاصرة الهيدروجينية بين المعقد وجزئية المذيب وحسبت كذلك الدوال التوان ويعود السبب في ذلك الى قلة الناتج الجزيئي لتداخل الايونات المتكون نتيجة الاصرة الهيدروجينية بين الايونات في المذيب وحسبت كذلك الدوال الترازة ويعود السبب في ذلك الى قلة الناتج الجزيئي لتداخل الايونات المتكون نتيجة الاصرة الهيدروجينية بين الايونات في المذيب وحسبت كذلك الدوال الترازة ويعود السبب في ذلك الى مالمدول و مرم المكافئ و مرم الموني و مالم مولي المحود في الايوني ، R: معدل المسافة بين الايونات في المحول ، فضلا عن حساب ناتج والدن لكل نسبة من المذيب وتم رسم العلاقة بين ($\Lambda_0 م$
