## Abstract

In any laboratory or field experiment, if homogeneity is provided on the experimental units, the Complete Random Design (CRD) is the best design, on the condition that the conditions (assumptions) for the analysis of variance (ANOVA) are available. If the homogeneity is not ensured, to control systematically one source of extraneous variability the Randomized Complete Block Design (RCBD) is the best. In the case of two sources of external variability, the Latin Square Design (LSD) design is best. If three sources of external variability are present, the Graeco Latin Square Design (GLSD) is better, but this design is complicated because of the two conditions available for the (GLSD) which is not to repeat letters for the rows and columns, and every letter must contain one Greek letter. In the case of  $6 \times 6$  design, we do not feel able to do this. Therefore, I have found a new technique for all designs that have odd numbers of ( $n$ ) treatments. This method can help researchers in their scientific research.

**Keywords:** CRD, RCBD, LSD, GLSD, Homogeneity, Normality, Correlation.

## 1. Introduction

The Graeco-Latin Square Design A Graeco-Latin square is a  $t \times t$  pattern that permits the study of  $t$  treatments simultaneously with three different blocking variables each at  $t$  levels. For example, the  $4 \times 4$  Graeco-Latin square shown in Table 1 is an extension of the Latin square design used earlier but with one extra blocking variable added. This is labelled  $\alpha$ ,  $\beta$ ,  $\gamma$ , and  $\delta$ , could be used to eliminate possible differences between, say four days on which the trials were run. It is constructed from the first two  $4 \times 4$  Latin squares. (Box et al., 2005)

In this arrangement, the treatments are grouped into replicates in three different ways with the consequence that the effects of three different sources of variation are equalised for all treatments. The additional grouping (usually represented by Greek letters) is denoted here by subscripts. Each treatment (A, B,...) appears once in each row and column and once with each index ( $\alpha, \beta, \dots$ ). (Cochran and Cox, 1957)

Graeco Latin squares are extensions of the basic Latin square designs, consider a  $t \times t$  Latin square, and superimpose on it a second  $t \times t$  Latin square in which the treatments are denoted by Greek letters, if the two squares when superimposed have the property that each Greek letters appear once and only once with each Latin letters, the two Latin squares are said to be orthogonal, and the design obtained is called a Graeco-Latin square. An example of a  $4 \times 4$  Graeco-Latin square is shown in Table 1. (Montgomery, 2017)

Table (1)  $4 \times 4$  Graeco-Latin square

| Row | Column     |            |            |            |
|-----|------------|------------|------------|------------|
|     | 1          | 2          | 3          | 4          |
| 1   | A $\alpha$ | B $\beta$  | C $\gamma$ | D $\delta$ |
| 2   | B $\delta$ | A $\gamma$ | D $\beta$  | C $\alpha$ |

|   |    |    |    |    |
|---|----|----|----|----|
| 3 | Cβ | Dα | Aδ | Bγ |
| 4 | Dγ | Cδ | Bα | Aβ |

## 2. Materials description

The Graeco Latin square design can be used to control systematically three sources of extraneous variability, that is, to block in three directions. The design allows investigation of four factors (rows, columns, Latin letters, and Greek letters), each at  $r$  levels in only  $r^2$  runs. Graeco-Latin squares exist for all  $r \geq 3$  except  $r = 6$ .

The statistical model is:

$$y_{ijkl} = \mu + \tau_i + \psi_j + \theta_k + \zeta_l + \varepsilon_{ijkl} \quad \begin{cases} i = 1, 2, \dots, r \\ j = 1, 2, \dots, r \\ k = 1, 2, \dots, r \\ l = 1, 2, \dots, r \end{cases}$$

Where:

$y_{ijkl}$ : is the observation in row  $j$  and column  $k$  for Latin letters  $i$  and Greek letters  $l$ ,

$\psi_j$ : is the effect of the  $j$ th row,  $\tau_i$  is the effect of Latin letters treatment  $i$ ,

$\theta_k$ : is the effect of Greek letters treatment  $k$ ,

$\zeta_l$ : is the effect of column  $l$ , and

$\varepsilon_{ijkl}$ : is a NID  $(0, \sigma^2)$  random error component. Only two of the four subscripts are necessary to completely identify an observation. (Cox and Reid, 2000) (Montgomery, 2017)

The analysis of variance is very similar to that of a Latin square. Because the Greek letters appear exactly once in each row and column and exactly once with each Latin letters, the factor represented by the Greek letters is orthogonal to rows, columns, and Latin letters treatments. Therefore, a sum of squares due to the Greek letters factor may be computed from the Greek letters totals, and the experimental error is further reduced by this amount. The null hypotheses of equal row, column, Latin letters, and Greek letters treatments would be tested by dividing the corresponding mean square by mean square error. The rejection region is the upper tail point of the  $F_{(\alpha; (r-1), (r-3)(r-1))}$  distribution. (Montgomery, 2017)

(Box et al., 2005)

Table (3) Analysis of Variance for a Graeco-Latin Square Design

| Source of Variation      | Degrees of Freedom | Sum of Squares                                                                                  | Mean Square Error                |
|--------------------------|--------------------|-------------------------------------------------------------------------------------------------|----------------------------------|
| Latin letters treatments | $r-1$              | $SS_L = \frac{\sum_{i=1}^r y_{i...}^2}{r} - \frac{y_{...}^2}{r^2}$                              | $MS_L = \frac{SS_L}{r-1}$        |
| Greek letters treatments | $r-1$              | $SS_G = \frac{\sum_{l=1}^r y_{...l}^2}{r} - \frac{y_{...}^2}{r^2}$                              | $MS_G = \frac{SS_G}{r-1}$        |
| Rows                     | $r-1$              | $SS_R = \frac{\sum_{j=1}^r y_{.j..}^2}{r} - \frac{y_{...}^2}{r^2}$                              | $MS_R = \frac{SS_R}{r-1}$        |
| Columns                  | $r-1$              | $SS_C = \frac{\sum_{k=1}^r y_{..k.}^2}{r} - \frac{y_{...}^2}{r^2}$                              | $MS_C = \frac{SS_C}{r-1}$        |
| Error                    | $(r-3)(r-1)$       | $SS_E = SS_T - SS_L - SS_G - SS_R - SS_C$                                                       | $MS_E = \frac{SS_E}{(r-3)(r-1)}$ |
| Total                    | $r^2-1$            | $SS_T = \sum_{i=1}^r \sum_{j=1}^r \sum_{k=1}^r \sum_{l=1}^r y_{ijkl}^2 - \frac{y_{...}^2}{r^2}$ |                                  |

(Winer, 1962)

### 3. Methodology and procedure

Design of odd number of square for any number of squares:

The problematic design in experimental design is Graeco Latin square, for example, in  $6 \times 6$  we cannot be able to do the design, we discovered this method it is used for any odd number of the square.

The stapes is semi-chess animation:

The 1<sup>st</sup> step systematic distribution, 2<sup>nd</sup> step replace the numbers to Greco letters and 3<sup>rd</sup> step Randomization for rows:

Figure (1) 3\*3 Graeco Latin Square Design

After that we do the randomization for the rows and the columns

|----|----|----|
| A1 | B3 | C2 |
| B2 | C1 | A3 |
| C3 | A2 | B1 |

Figure (2) randomisation for 3\*3 Graeco Latin Square Design

The first stapes we must distribute the Latin Letters on the table systematically in the first row (A, B, and C) in the second row (B, C, and A) and (C, A, and B) for the last row in 3×3 square. After that we must distribute the Graeco Letters on the Latin Letters the condition must every Latin square must be Receive diffident Graeco Letters, The stapes must be started in the middle of the square (A1) after that the second animation like the knight animation in chess ♞ like the L Letters  $\uparrow$  (A2) after that  $\downarrow$  (A3) the third stapes is Like the Bishop move in the chess ♞ and diagonal moving  $\nearrow$  and give the new order numbers from 1 to 3 (C1,C2 and C3) after that we do the last stapes it's the Rook moves ♞ to the right (B1) and complete the knight moving to down  $\downarrow$  (B2) and the previous is  $\uparrow$  (B3). Moreover, the below example about 5×5 to 11×11 and we can able to do any odd square by this way.

Figure (8) 13\*13 Graeco Latin Square Design

#### 4. Results

The accuracy of the results depends to a great extent on the design and analysis of the experiment. The more accurate results can be obtained, the better the decisions are. The designs used vary according to the nature of the experiment. Each of these designs fits a specific goal. This design or that, and the experience may be simple or complex.

One of the most challenging designs and the creation of the design is the design of the GLSD (Graeco Latine Square Design), because the design requires not to repeat the Latin and Greek letters once in the row, and column with another condition is not to repeat the Latin with Greek letters only once in any experimental unit, it is difficult. In the design  $6 \times 6$  cannot provide this condition so cannot apply with this design, I managed to find a way to fit all the designs in the case of the number of individual transactions  $n \times n$  odd number of treatments.

## 5. Discussion

We can use this technique for any  $n \times n$  odd number of (rows, columns or treatments (Latin letters or Greco letters)).

In conclusion programming the proposed method in advanced statistical packages, such as Minitab, Matlab, Statgraphics, R, and SPSS.

## ملخص

في أي تجربة مختبرية أو حقليّة إذا تم توفير التجانس على الوحدات التجريبية فإن التصميم العشوائي الكامل (CRD) هو أفضل تصميم شريطة توفر شروط تحليل التباين، أما إذا لم يتم توفير التجانس بوجود اختلاف باتجاه واحد فإن تصميم القطاعات الكاملة العشوائية (RCBD) هو الأفضل، أما في حالة وجود الاختلاف باتجاهين فإن التصميم المربع اللاتيني (LSD) هو الأجدر، وفي حالة وجود الاختلاف بثلاث اتجاهات فإن تصميم المربع اللاتيني الاغريقي (GLSD) هو الأمثل، لكن التصميم المربع الاغريقي يعد من التصميمات المعقدة للشروط الواجب توفرها على التصميم بحيث يتكرر كل معاملة مرة واحدة في الصف والعمود، ويختار كل معاملة حرف اغريقي واحد، حيث لا يتكرر في الصف والعمود ومع المعاملات لهذا السبب ولا يمكن تصميم حالة  $6 \times 6$  لفقدان الشروط المذكورة، لذلك قام البحث بايجاد طريقة مبتكرة للتصاميم التي تكون عدد معاملاتها فردية الى العدد (ن) من المربعات الفردية، وهذه الطريقة يمكن ان تساعد الباحثين في تصميم بحوثهم العلمية والإفادة منها.
